Normal  
blood vessels  
A= artery  
V= vein

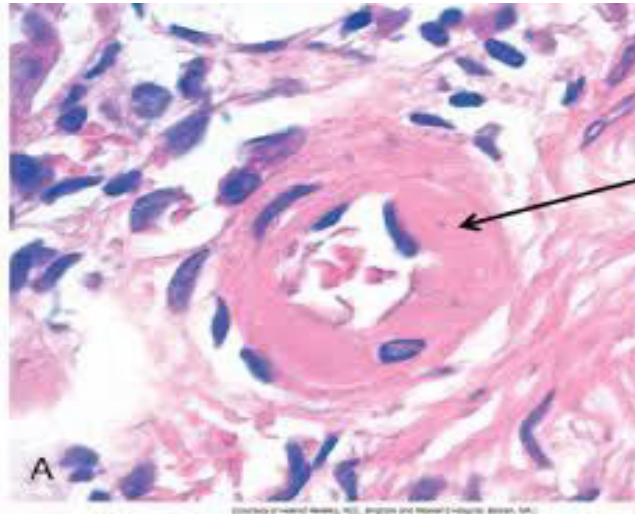

# ARTERIOSCLEROSIS

- *Arteriosclerosis* literally means "hardening of the arteries"
- It reflects arterial wall thickening and loss of elasticity.
- Three patterns are recognized, with different clinical and pathologic consequences:

# *1-Arteriolosclerosis*

- affects small arteries and arterioles.
- is most often associated with hypertension and/or diabetes mellitus

## *2-Mönckeberg medial calcific sclerosis*

- is characterized by calcific deposits in muscular arteries
- typically in persons older than age 50.
- radiographically visible
- often palpable calcifications
- do **not** encroach on the vessel lumen and are usually not clinically significant

## **2-Mönckeberg medial calcific sclerosis**

# 3-Atherosclerosis

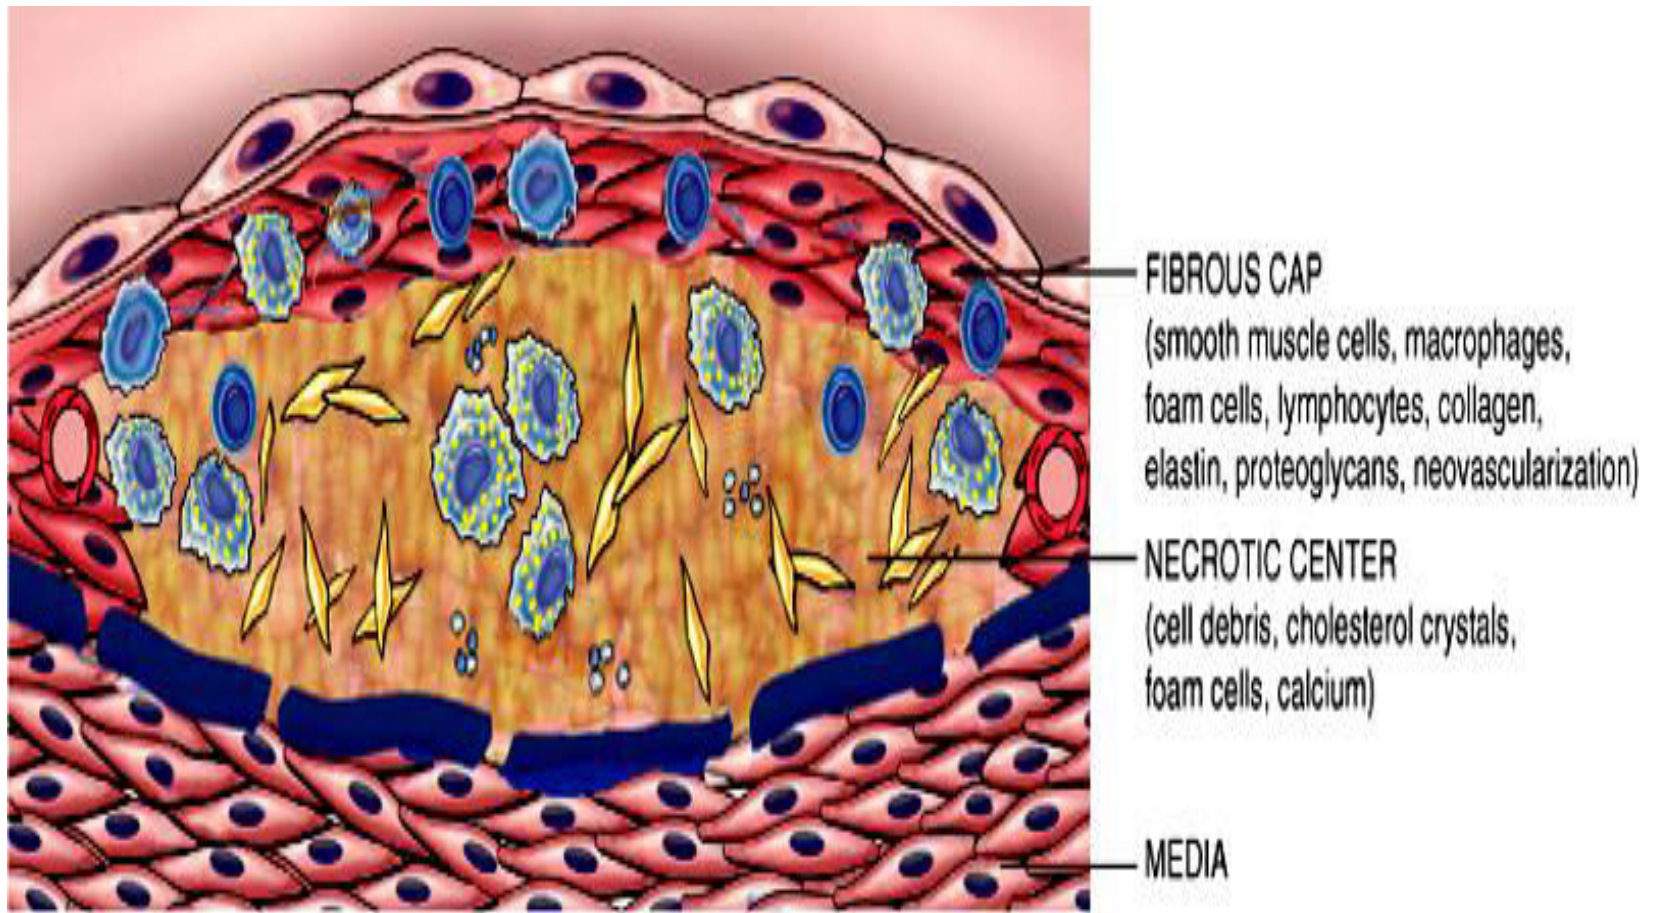

- from Greek root words for "gruel" and "hardening,"
- is the most frequent and clinically important pattern
- characterized by intimal lesions called ***atheromas*** (also called *atherosclerotic plaques*), that protrude into vascular lumina.
- An atheromatous plaque consists of a raised lesion with a soft, yellow, grumous core of lipid (mainly cholesterol and cholesterol esters) covered by a firm, white fibrous cap

# Pathogenesis

- The atherosclerotic process is not fully understood.
- Atherosclerosis is initiated by inflammatory processes in the endothelial cells of the vessel wall associated with retained [low-density lipoprotein](#) (LDL) particles.
- This retention may be a cause, an effect, or both, of the underlying inflammatory process

- LDL particles and their content are susceptible to oxidation by [free radicals](#)
- This will lead to endothelial stimulation and initiation of inflammatory process.

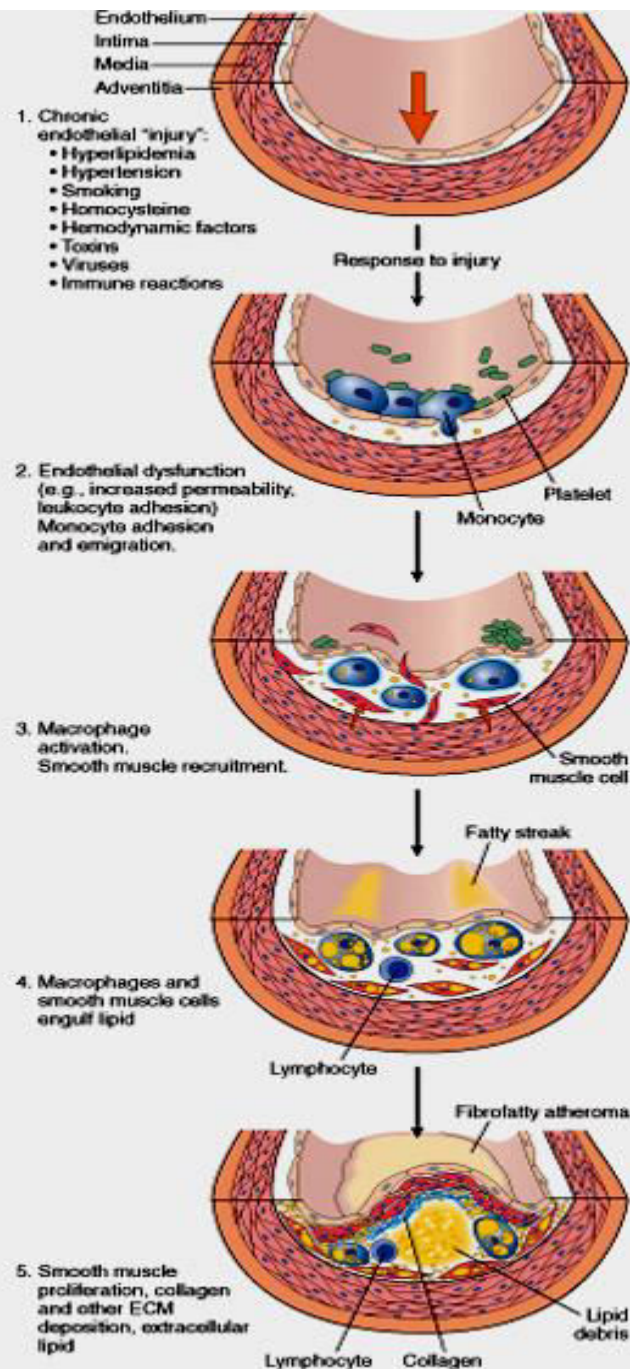

# The major components of a well-developed intimal atheromatous plaque

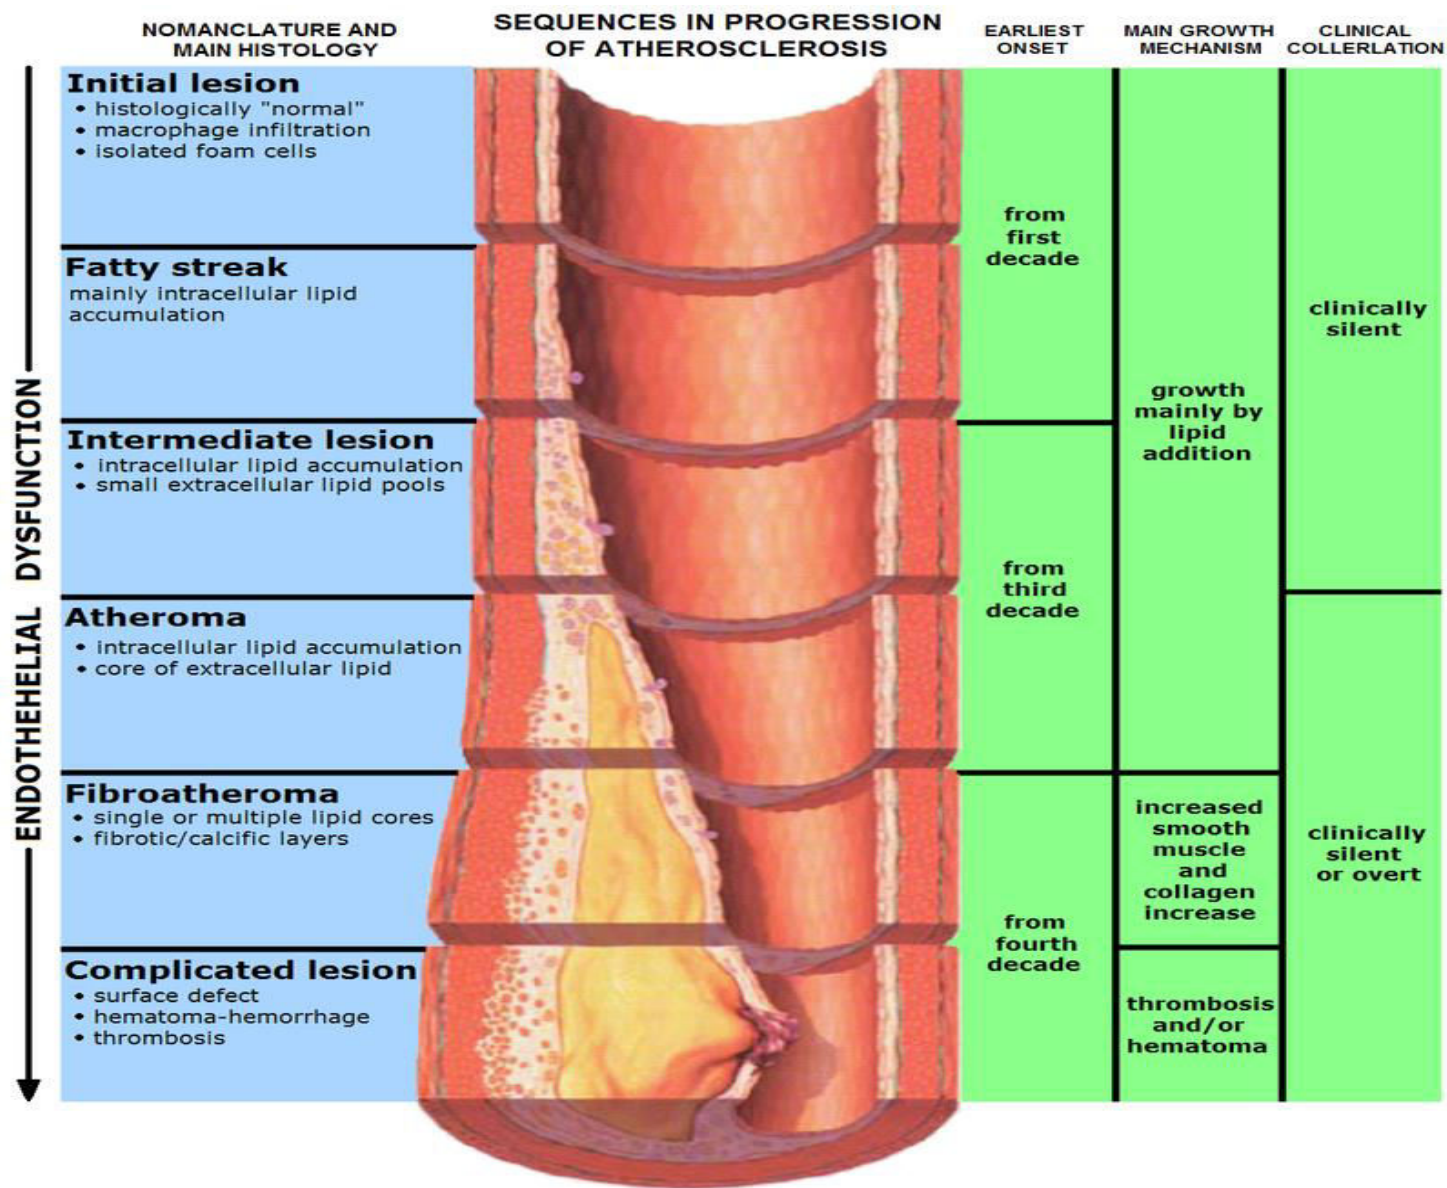

# Atheromatous plaque

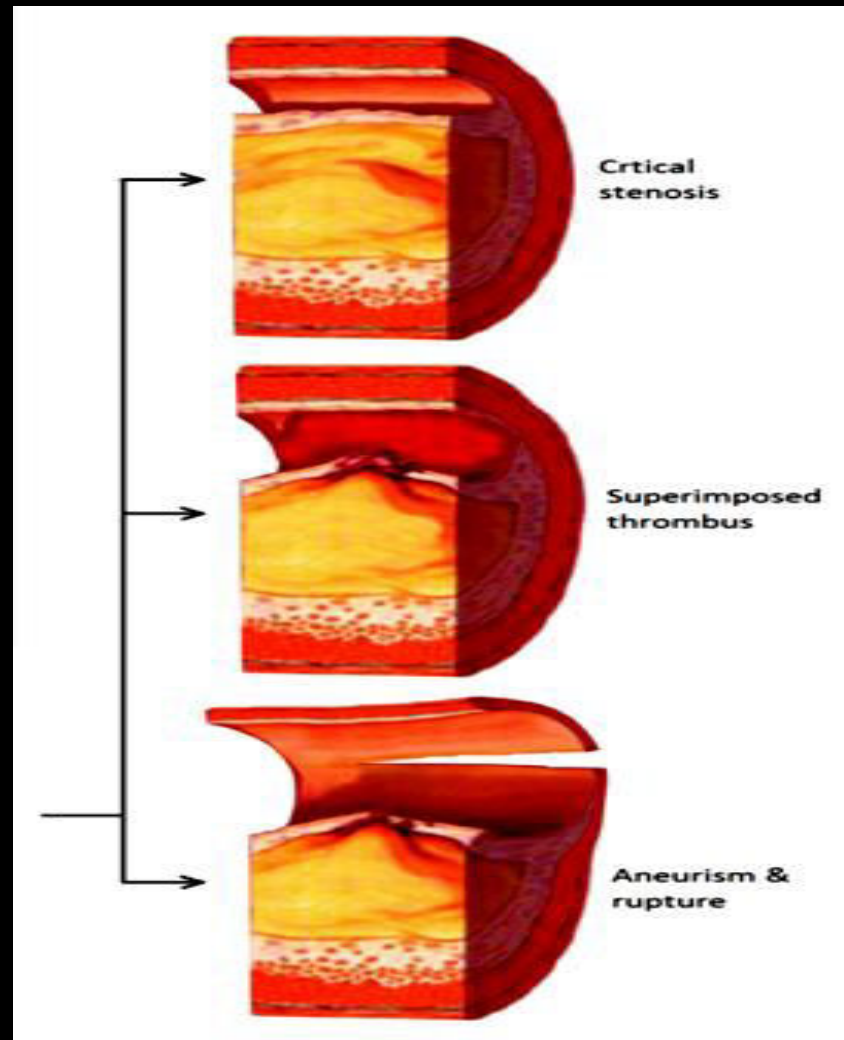

# Formation of atheromatous plaque

# Atherosclerosis progression

# Epidemiology

- atherosclerosis is much less prevalent in Central and South America, Africa, and Asia.
- The mortality rate for IHD in the United States is among the highest in the world and is approximately five times higher than that in Japan.
- Nevertheless, IHD has been increasing in Japan and is now the second leading cause of death there. Moreover, Japanese who immigrate to the United States and adopt American *lifestyles and dietary customs* acquire the same predisposition to atherosclerosis as the homegrown population.

- *Multiple risk factors have a multiplicative effect:* 2 risk factors increase the risk 4X. E.g. if 3 risk factors are present (e.g., hyperlipidemia, hypertension, and smoking), the rate of myocardial infarction is increased 7X.

# Risk Factors for Atherosclerosis

<b>Major Risks</b>	<b>Lesser, Uncertain, or Non-quantitated Risks</b>
<b>Nonmodifiable</b>	<b>Obesity</b>
<b>Increasing age</b>	<b>Physical inactivity</b>
<b>Male gender</b>	<b>Stress ("type A personality")</b>
<b>Family history</b>	<b>Postmenopausal estrogen deficiency</b>
<b>Genetic abnormalities</b>	<b>High carbohydrate intake</b>
	<b>Lipoprotein(a)</b>
<b>Potentially Controllable</b>	<b>Hardened (trans)unsaturated fat intake</b>
<b>Hyperlipidemia</b>	
<b>Hypertension</b>	<b>Chlamydia pneumoniae infection</b>
<b>Cigarette smoking</b>	
<b>Diabetes</b>	
<b>C-reactive protein</b>	

# **Major Constitutional Risk Factors for atherosclerosis**

- **Major Risks (*Nonmodifiable*):**

- \*Increasing age
- \*Male gender
- \*Family history
- \*Genetic abnormalities

- ***Potentially Controllable/modifiable:***

- Hyperlipidemia
- Hypertension
- Cigarette smoking
- Diabetes

## 1-age

- Between ages 40 and 60, the incidence of myocardial infarction in men increases 5 times.
- Death rates from IHD rise with each decade even into advanced age.

## 2-Gender

- Premenopausal women are relatively protected against atherosclerosis compared with age-matched men.
- MI and other complications of atherosclerosis are uncommon in premenopausal women unless they are otherwise predisposed by diabetes, hyperlipidemia, or severe hypertension.
- After menopause, the incidence of atherosclerosis-related diseases increases and with greater age eventually exceeds that of men

# 3-Genetics

- well-established familial predisposition to atherosclerosis and IHD is **multifactorial**.
- In some instances it relates to:
- **familial clustering** of other risk factors, such as hypertension or diabetes; or :
- **well-defined genetic derangements in lipoprotein metabolism**,
  - e.g. familial hypercholesterolemia that result in excessively high blood lipid levels.

# **Additional Risk Factors for atherosclerosis**

- 20% of all cardiovascular events occur in the absence of any major risk factor

**1-Inflammation as marked by C-reactive protein**

**2-Hyperhomocystinemia**

**3-Lipoprotein a**

**4-Factors Affecting Hemostasis**

- **Other Risk Factors**

**1-lack of exercise**

**2-competitive, stressful lifestyle ("type A" personality)**

**3-obesity**

**4-Postmenopausal estrogen deficiency**

**5-High carbohydrate intake**
